Chapter 1

Math Review

1.1 Linear Algebra

Concepts:

- scalar, vector, matrix, tensor(n-rank tensor, matrix is a rank 2 tensor)
- Gaussian Elimination, rank
- p-norm

$$|X|_p = \left(\sum_i |x_i|^p \right)^{\frac{1}{p}}$$

- inner product $\langle x_i, y_i \rangle$, outer product
- orthogonal dimension, basis, orthogonal basis
- linear transformation $Ax = y$
- eigenvalue, eigenvector $Ax = \lambda x$ (transformation and speed)
- vector space, linear space(with summation, scalar production), inner product space(inner product space)

1.2 Probability

Concepts:

- Classic Probability Model: Frequentist
- Bayesian Probability Theory
- Random variable, continuous RV, discrete RV, probability mass function, probability density function, cumulative density function
- Bernoulli distribution, Binomial distribution(n,p)

$$P(X = k) = \binom{N}{k} p^k (1-p)^{(n-k)}$$

, Poisson distribution

$$P(X = k) = \lambda^k \frac{e^{-\lambda}}{k!}$$

- uniform distribution, exponential distribution

$$e^{-\frac{x}{\theta}} \theta, P(x > s+t | X > s) = P(x > t)$$

, normal distribution, t-distribution

- expectation, moments, variance, covariance, correlation coefficient

Theorems:

- Law of Total Probability
- Bayes' Rule

$$P(H|D) = \frac{P(D|H)P(H)}{P(D)}$$

P(H)-prior probability, P(D—H)-likelihood, P(H—D)-posterior probability,

1.2.1 Important Distributions, Moment Generating Functions

1. Normal Distribution, See next chapter
2. Bernoulli Distribution
3. Exponential Distribution $f_x(x, \theta) = \theta e^{-\theta x}$
4. Poisson Distribution

1.3 Information Theory

Concepts:

- Information

$$h(A) = -\log_2 p(A)$$

(bit)

- (Information Source) Entropy

$$H(X) = -\sum_{i=1}^n p(a_i) \log_2 p(a_i) \leq \log_2 n$$

Maximize under equal probability

- Conditional Entropy

$$H(Y|X) = -\sum_{i=1}^n p(x_i) H(Y|X = x_i) = -\sum_{i=1}^n p(x_i) \sum_{j=1}^n p(y_j|x_i) \log_2 p(y_j|x_i)$$

$$= \sum_{i=1}^n \sum_{j=1}^n p(x_i, y_j) \log_2 p(y_j|x_i)$$

- Mutual Information/Information Gain

$$I(X; Y) = H(Y) - H(Y|X)$$

- Kullback-Leibler Divergence (K-L) Divergence

$$D_{KL}(P||Q) = \sum_{i=1}^n p(x_i) \log_2 \frac{p(x_i)}{q(x_i)} \neq D_{KL}(Q||P)$$

$$D_{KL}(f, \hat{f}) = \int_{-\infty}^{\infty} \log\left(\frac{f_X(x)}{\hat{f}(x)}\right) f_X(x) dx$$

Measures the Distance of two distributions. The optimal encoding of information has the same bits as the entropy. Measures the extra bits if the real distribution is q rather than p . (Using P to approximate Q) K-L divergence plays an important role in both information theory and MLE theory. MLE $\hat{\theta}$ is actually finding the closest K-L Distance approximation of $f(x; \theta)$ to sample distribution.

Theorems:

- The Maximum Entropy Principle. Without extra assumption, max entropy/equal probability has the minimum prediction risk.

1.4 Optimization Theory

- Objective function/Evaluation function, constrained/unconstrained optimization Feasible Set, Optimal Solution, Optimal Value, Binding Constraints, Shadow Price, Infeasible Price, Infeasibility, Unboundedness
- Linear Programming
- Lagrange Multiplier

$$L(x, y, \lambda) = f(x, y) + \lambda \varphi(x, y)$$

- Convex Set, Convex Function $f : S \rightarrow R$ is convex if and only if $\nabla^2 f(\mathbf{x})$ is positive semidefinite

Optimization Methods:

- Linear Search Method: Direction First, Step Size second
 - Gradient Descent: Batch Processing(Use all samples) vs Stochastic Gradient Descent(Use one sample)
 - Newton's Method: Use Curvature Information
- Trust Region: Step first, direction second. Find optimal direction of second-order approximation. If the descent size is too small, make step size smaller.
- Heuristics Method
 - Genetic Algorithm
 - Simulated Annealing
 - Partical Swarming/Ant Colony Algorithm

Theorems:

-

1.5 Formal Logic

Concepts

- Generative Expert System: Rule+Facts+Deduction Engine
- Godel's incompleteness theorems

Chapter 2

Statistics

2.1 Concepts

2.1.1 Basic

- parameter(constant for probability model), statistic (model of sample data), data, sample, population
- point estimation, interval estimation, Confidence Interval(
 $P(L \leq \theta \leq U)$, notice: θ is not random, L, U is random! (We repeat constructing confidence interval a n times, α percent of the times, it will contain *theta*.

2.1.2 Estimator and Estimation

- Method of Moments: $E(X^k)$ based on LOLN.
If We have p parameters, we can use p moments to form a system of equations to solve $\theta_1, \dots, \theta_p$

$$\sum_{i=1}^n X_i^j = E(X^j)$$

, for $j = 1, \dots, p$

- Maximum Likelihood Estimation. Multiply p.m.f/p.d.f since every sample is independent. Maximize the likelihood of finding samples.

If $X_1, \dots, X_n \stackrel{i.i.d}{\sim} f_x(x, \theta)$,

$$l(\theta) = \prod_{i=1}^n f_{X_i} f_{x_i}(x_i; \theta), L(\theta) = \log l(\theta)$$

$$\hat{\theta}_{MLE} = \operatorname{argmax}_{\theta} f_x(x; \theta) = \operatorname{argmax}_{\theta} L(\theta)$$

Analytical or Numerically solved.

$$\frac{\partial}{\partial \theta} [\log L(\theta)] = 0, \frac{\partial^2}{\partial \theta^2} [\log L(\theta)] < 0$$

, for multiple parameters, we need the Hessian matrix to be negative definite $x^t H x < 0, \forall x$

- Properties of MLE

1. Invariance $\hat{\theta}$ is MLE of θ , then $g(\hat{\theta})$ is MLE of $g(\theta)$
2. Consistency

$$P(\hat{\theta} - \theta) \rightarrow 0$$

as $n \rightarrow \infty, \forall \epsilon > 0$ Under the conditions

- (a) $X_1, \dots, X_n \stackrel{i.i.d}{\sim} f_x(x|\theta)$
 - (b) parameters are identifiable, $\theta \neq \theta', f_x(x|\theta) \neq f_x(x|\theta')$
 - (c) densities $f_x(x|\theta)$ has common support (set of x with positive density/probability), $f_x(x|\theta)$ is differentiable at θ
 - (d) parameter space Ω contains open set ω where true θ_0 is an interior point
3. Asymptotic Normality

$$\sqrt{n}(\hat{\theta}_{MLE} - \theta_0) \rightarrow N(0, I^{-1}(\theta_0))$$

$$I(\theta_0) = E(-(\frac{\partial}{\partial \theta} [\log f(x, \theta)]))^2 = E(-\frac{\partial^2}{\partial \theta^2} [\log f(x, \theta)])$$

called the Fisher Information

$$\hat{\theta}_{MLE} \approx N(\theta_0, \frac{1}{nI(\theta_0)})$$

$$nI(\theta_0) = E(-\frac{\partial^2}{\partial \theta^2} \log L(\theta))$$

So the Variance of MLE($1/E(-\frac{\partial^2}{\partial \theta^2} \log L(\theta))$) is the reciprocal of amount of curvature at MLE.

Usually, We can just use the *observed Fisher Information* (curvature near θ_{MLE}) instead. ($I(\theta_{MLE})$)
 $\frac{1}{nI(\theta_0)}$ is called Cramer-Rao Lower Bound.

Under Multi-dimensional Case,

$$I(\theta_0)_{ij} = E\left(-\frac{\partial^2}{\partial \theta_i \partial \theta_j} [\log f(x, \theta)]\right)$$

$Hessian \approx nI(\theta_0)$ $Hessian^{-1} \approx nI(\theta_0)$ when we use numerical approach.

Under the above four conditions plus

- (a) $\forall x \in \chi$, $f_x(x|\theta)$ is three times differentiable with respect to θ , and third derivative is continuous at θ , and $\int f_x(x|\theta)dx$ can be differentiated three times under integral sign
- (b) $\forall \theta \in \Omega$, $\exists c, M(x)$ (both depends on θ_0) such that

$$\frac{\partial^3}{\partial \theta^3} [\log f(x, \theta)] \leq M(x), \forall x \in \chi, \theta_0 - c < \theta < \theta_0 + c, E_{\theta_0}[M(x)] < \infty$$

- Δ -Method: $g(\hat{\theta}_{MLE})$ is approximately

$$N(g(\theta), (g'(\theta))^2 \frac{1}{nI(\theta)})$$

if asymptotic normality is satisfied.

In Multivariate Case:

$$\hat{\theta} \sim N(\theta, \Sigma/n), \theta, \hat{\theta} \in R^p$$

$$g : R^p \rightarrow R^m$$

$$g(\hat{\theta}) \sim N(g(\theta), G \Sigma G^T / n)$$

$$G = \begin{pmatrix} \frac{\partial g_1(\theta)}{\partial \theta_1} & \dots & \frac{\partial g_1(\theta)}{\partial \theta_p} \\ \vdots & \ddots & \vdots \\ \frac{\partial g_m(\theta)}{\partial \theta_1} & \dots & \frac{\partial g_m(\theta)}{\partial \theta_p} \end{pmatrix}$$

- Estimation criteria

– Unbiased $E(\hat{\theta}) = \theta$

- Minimum Variance (MVUE, minimum variance unbiased estimator) $Var(\hat{\theta}) < Var(\theta')$
- Efficient
- Coherent

2.1.3 Model Selection

AIC - Akaike Information Criterion

By K-L Distance

$$\begin{aligned}
 D_{KL}(f, \hat{f}) &= \int_{-\infty}^{\infty} \log\left(\frac{f_X(x)}{\hat{f}(x)}\right) f_X(x) dx \\
 &= \text{const} + \frac{1}{2} \int (-2 \log \hat{f}(x)) f(x) dx = \text{const} + AIC \\
 A(f, \hat{f}) &= -2 \log L(\theta) + 2p\left(\frac{n}{n-p+1}\right)
 \end{aligned}$$

2.1.4 Hypothesis Testing

- Hypotheses, Test Statistic(T), Rejection Region
- p-value (chance of rejecting, largest choice of α that we would fail to reject H_0)
- type-I error(wrongly reject), type-II error(wrongly accept)

Hypothesis Testings (Based on the distribution of $\hat{\theta}$)

- Wald Test

$$\begin{aligned}
 T &= \frac{\hat{\theta} - \theta_0}{Se(\hat{\theta})} \\
 \hat{\theta}_{MLE} &\approx N\left(\theta_0, \frac{1}{nI(\theta_0)}\right) \\
 T &= \frac{\hat{\theta} - \theta_0}{\sqrt{\frac{1}{nI(\theta_0)}}}
 \end{aligned}$$

- Likelihood Ratio Test
- Score Test

*Computation-based hypothesis testing approach

- Permutation tests:
Test $X_1, \dots, X_n \sim F, Y_1, \dots, Y_n \sim G$, if $F = G$. Use $T = \text{Mean}(X_i) - \text{Mean}(Y_i)$, each time scramble X and Y labels and should not change the distributions of vectors $X_1, \dots, X_n, Y_1, \dots, Y_n$
- Bootstrapping:
 $X_1, \dots, X_n \sim F$ with $T = T(X_1, \dots, X_n)$, to get the distribution of T, **sample with replacement**. The belief is $(\hat{\theta} - \theta)$ should behave the same as $(\theta^* - \theta)$. The first quantity can be treated like a pivot. (use $(\theta^*_1 - \hat{\theta}_1), \dots, (\theta^*_n - \hat{\theta}_n)$ to test.

Multiple Testing

- Family-wise Error Rate(FWER) the probability of rejecting at least one of at least one null hypothesis
Under independence, the probability of making mistake when all null are true: $(P(\text{any type I mistake}) = 1 - P(\text{no type I mistake for all}) = 1 - (1 - \alpha)^M = \beta)$
- Bonferroni correction, assuming independence
 $P(\bigcup_{i=1}^n \text{type I mistake}) \leq \sum_{i=1}^n P(\text{type I mistake}) \leq M\alpha$, control at $\alpha = \frac{\alpha}{M}$
 α being too small will impact power of the individual tests!
- False Discovery Rate(FDR): bound the fraction of type-I errors. R be the total number of hypotheses rejected. V be the number of rejected hypotheses that were actually null. Let $FDR = V/\max(R, 1)$, control $E(FDR) \leq \alpha$.

2.2 Theorems

- Law of Large Number

- Central Limit Theorem
- Bias/Variance decomposition (error = bias + variance + noise)

$$\begin{aligned}
 MSE(\mu(X)) &= E[(Y - \hat{\mu}(X))^2] = E[(Y - f(x) + f(x) - \hat{\mu}(X))^2] \\
 &= E[(Y - f(x))^2 + 2E[(Y - f(x))(f(x) - \hat{\mu}(X))] + E[(f(x) - \hat{\mu}(X))^2] \\
 &= E[(Y - f(x))^2] + 2E[(Y - f(x))(f(x) - \hat{\mu}(X))] + E[(f(x) - \hat{\mu}(X))^2] \\
 &= \sigma_x^2 + Bias(\hat{\mu}(X))^2 + Var(\hat{\mu}(X))
 \end{aligned}$$

2.3 Important Distributions

1. Normal Distribution, $X_1, \dots, X_n \sim N(\mu, \sigma^2)$ then

- (a) \bar{X} and s^2 are independent
- (b) $\frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \sim N(0, 1)$
- (c) $\frac{(n-1)s^2}{\sigma^2} \sim \chi_{n-1}^2$
- (d) $\frac{\bar{X} - \mu}{s/\sqrt{n}} = \frac{\frac{\bar{X} - \mu}{\sigma/\sqrt{n}}}{\frac{(n-1)s^2}{\sigma^2} \frac{1}{\sqrt{n-1}}} \sim t_{n-1}$

2. Multi-variate normal distribution

$$f_x(x) = \frac{1}{(2\pi)^{p/2} |\Sigma|^{1/2}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1}(x - \mu)\right)$$

- (a) X_1, \dots, X_n normal $\Leftrightarrow (X_1, \dots, X_n)$ is multivariate normal. (Not equivalent)
 - (b) $E(X) = \mu, Var(X) = \Sigma$
 - (c) Linear transformations $AX + b \sim N(A\mu + b, A\Sigma A^T)$ remain multivariate normal
 - (d) Marginals are multivariate normal, each sub-vector is multivariate normal, the parameters are just sub-matrices.
 - (e) All conditionals are multivariate normal
3. t-distribution: like normal distribution, but heavier tails

- (a) $Z \sim N(0, 1), Y \sim \chi_\nu^2, Z, Y$ independent,

$$X = Z/\sqrt{Y/\nu} \sim t_\nu$$

- (b) pdf has polynomial tails (decays much slower than exponential ones)
- (c) $\nu = 1$, it is the **Cauchy Distribution**, with very heavy tails (no expectation)
- (d) The MCF not exist. $E(|X|^k) < \infty$ for $k < \nu$, $E(|X|^k) = \infty$ for $k > \nu$
- (e) $X \sim t_\nu, E(X) = 0, Var(X) = \frac{\nu}{\nu-2}$

$$f_X(x) = \frac{1}{\pi(1+x^2)}$$

4. χ^2 distribution

$$f_x(x) = \frac{1}{(2^{k/2}\Gamma(k/2))} x^{\frac{k}{2}-1} e^{-\frac{x}{2}}, x \in [0, \infty) \sim Gamma(\frac{k}{2}, \frac{1}{2})$$

- (a) $E(X) = k, Var(X) = 2k, M_X(t) = (\frac{1}{1-2t})^{k/2}$
- (b) $X \sim N(0, 1) \Rightarrow X^2 \sim \chi^2, X_1, \dots, X_n \sim N(0, 1) i.i.d \Rightarrow \sum X_i^2 \sim \chi^2,$

$$f_X(x) = \frac{1}{\pi(1+x^2)}$$

5. F-Distribution

More Generalized Distributions

1. Generalized Error Distribution (symmetric)
2. Non-standard t-distribution (shift and scaling, heavy tailed, symmetric)
3. Theodossious skewed t-distribution
4. Theodossious skewed t-distribution plus shift

2.4 Practice/Examples

1. sample mean(\bar{X}) is unbiased. Sample variance ($\frac{1}{n-1} \sum_{i=1}^n x_i^2$) is unbiased. But sample std is not unbiased. $SE(\bar{X}) = \frac{\sigma^2}{n}$

2. $\hat{Cov}(X, Y) = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})(X_i - \bar{Y})$ is unbiased
3. Distributions with Expectation not exist? (Cauchy)
4. Common Confidence Intervals:
 μ : $P(-t_{\alpha/2, n-1} \leq \frac{\bar{X} - \mu}{s/\sqrt{n}} \leq t_{\alpha/2, n-1}) = 1 - \alpha$,
 σ : $P(a \leq \frac{(n-1)s^2}{\sigma^2} \leq b) = 1 - \alpha$
5. Solve MLE/MOM for beta, exponential ($n/\sum X_i$, normal
6. * prove Asymptotic Normality of MLE(hint: using Taylor Expansion for $\theta, \hat{\theta}$)
7. * Use t^{th} quantile to approximate c.d.f, what's the distribution?
 $(Y_n = \frac{1}{n} \sum I(X_i < x), \text{ a Bernoulli distribution with } p = F_x(x),$
 $\sqrt{n}[Y_n(x) - F_x(x)] \sim N(0, F(x)(1 - F(x)).$
8. $X_1, \dots, X_n \sim \text{Binomial}(n, p)$, What's the MLE for p and Fisher Information? ($\hat{p} = \frac{x_i}{n}, I(p) = 1/p(1-p), var(p) = \frac{p(1-p)}{n}$)
9. $(x_i, y_i) \sim N(\mu_i, \sigma^2)$, find MLE for σ ($\frac{1}{4N} \sum (x_i - y_i)$)
10. How can you get $N(0,1)$ random variables from $U[0,1]$? (Method1: Inverse Transformation, Method2; Use
 $Sum Z_i^2 \sim \chi_k^2, k=2, F^{-1}(u) = -2\log(1-u),$
 $R^2 \sim \chi^2, Z_1 = R\cos\theta, Z_2 = R\sin\theta, \theta \in [0, 2\pi]$
11. (Permutation test) how can you test $X_1, \dots, X_n \sim F$, how can you test if F is symmetric? (Multiply -1 on all two form two sample groups)
12. Draw a bootstrap sample, what fraction of original data points appear in this sample on average?
 Define I be the indicator is it is in the sample.
 $E(\frac{1}{n} \sum I_i) = E(I_i) = P(\text{ith point shows up}) = 1 - (1 - \frac{1}{n})^n$

Chapter 3

Bayesian Statistical Theory

Bayes' Rule

$$f_{Y|X}(y|x) = \frac{f_{(X,Y)}(x,y)}{f_X(x)} = \frac{f_{(X,Y)}(x,y)}{\int f(x|y)f(y)dy}$$

Bayesian Inference:

All parameters are random variables,

$$\pi(\theta|x) = \frac{f(x|\theta)\pi(\theta)}{\int f(x|\theta)\pi(\theta)d\theta}$$

$$\pi(\theta|x) \sim f(x|\theta)\pi(\theta)$$

$\pi(\theta)$ is the prior distribution, $\pi(\theta|x)$ is the posterior distribution for θ given x .

Bayes Estimator

$$\hat{\theta}_{Bayes} = E(\theta|X) = \int \theta \pi(\theta|X) d\theta$$

Conjugate Distribution: $f(x), \pi$ is called conjugate distributions if model $\pi(\theta|x), \pi(\theta)$ follows the same Distribution

eg. Bernoulli(θ) and Beta(α, β), ($\pi(\theta|x) \sim \text{Beta}(\alpha + \sum X_i, \beta + n - \sum X_i)$)
($f(x|\theta) = \prod_{i=1}^n f_{X_i}(X_i|\theta)$)

$$\hat{\theta}_{Bayes} = E(\theta|X) = \frac{\alpha + \sum X_i}{\alpha + \beta + n}$$

$$= \frac{\sum X_i}{n} \frac{n}{\alpha + \beta + n} + \frac{\alpha}{\alpha + \beta} \frac{\alpha + \beta}{\alpha + \beta + n}$$

The prior mean (second term) influences less as n grows.

Poisson(θ) and $\text{Gamma}(\alpha + \sum X_i, \beta + n)$

3.1 Bayesian Decision Theory

In State ω we take action $a \in A$, incurr Loss $L(\omega, a)$, how to choose a?

Risk:

$$R(a|x) = \sum_{j=1}^k L(\omega_j, a) P(\omega_j|x)$$

Decision Rule $d \in A$

$$d^*(x) = \arg \min_{a \in A} R(a|x)$$

Chapter 4

Computational Learning Theory

Part II

Supervised Learning Models

Chapter 5

Basic Data Science and Data Wrangling Knowledge

Basic Transformations

- Box-Cox Transformation -useful when response is strictly positive

$$y = \begin{cases} \frac{y^\lambda - 1}{\lambda}, & \text{if } \lambda \neq 0 \\ \log(y), & \text{if } \lambda = 0, \end{cases}$$

-

Chapter 6

Regression Overview and Linear Regression

6.1 Overview

6.1.1 Type of Models

All Basic Models begins with **Linear Regression** Because

- Linear relationship is the simplest relationship other than constant relationship or "null" model (average)
- It's a global model
- Data Invariance: Simple linear model don't do any pre-processing or transformation on the covariants.
- Very Explainable, limited interpretation power.

So, the alternation/improvements also focuses on these aspects

- Nonlinear features-Introduction of basis function
 - Polynomial Regression

- Spline Models(eg. Cubic Spline, Smoothing Spline)
- Nonlinear parameters: Parameters Self-adjusting.(activation function is an example of basis function as well)
 - Neutral-Network
- global nonlinear: global nonlinear on both parameters and features achieved by linkage function, extends regression models to classification.
 - Generalized Linear Model
- Change the global model to a local model
 - Local Regression (Regression + KNN)
 - Nonparametric Regression
 - Kernel Function
 - Distance Based Learning
- Data Preprocessing (Transformation) and Dimension Reduction
 - PCA
 - LDA
 - Manifold Learning
- Improve Generalization Capability from outside (not from inside the model)
 - Regularization Methods(eg. Ridge, Lasso)
 - Ensemble Learning(Stacking, Aggregating): Random Forest, Boosting(GBDT), Deep Learning...

6.1.2 The Key Questions

- What assumptions are the model making
- How will we access the validity of those assumptions
- How can we be confident about out-of-sample fitting (overfitting problem)
- How do we make predictions and quantify the uncertainty in models?

6.2 Linear Regression

Common Terms

1. Independent Variable, Features, Covariates, Predictors
2. Dependent Variable, Response, Output (variable)
3. Scaling - transform a variable to have mean zero and variance one

6.2.1 Assumptions

Classic Assumptions for Statistics:

1. Linear Relationship between covariates and dependent variable
2. $E(\varepsilon) = 0$
3. $Var(\varepsilon) = \sigma^2$: Homoscedasticity
4. ε is independent with covariates
5. x is observed without error (and no perfect multicollinearity in multivariate case)
6. (optional, Gauss-Markov Theorem) ε is normal - when it is, OLS and MLE agrees and to be BLUE(Best Linear Unbiased Estimator)

Testing the Assumptions of Linear Regression

- Scatter Plot
Linear Relationship and Outliers
- Residual Analysis $\hat{\varepsilon} = y - \hat{y}$
Diagnostic Plots:
 1. Plot of Residuals vs. Fitted Values
 2. Normal Probability Plot
 3. Plot Residuals versus time (see any trend of fit)

- Cook's Distance

$$D_j = \frac{\sum_{i=1}^n (\hat{y}_i - \hat{y}_{i(-j)})^2}{(p+1)\hat{\sigma}^2}$$

Test Against $F_{(p+1), (n-p-1)}$ degrees of freedom, over 50th percentile will definitely become a problem

6.2.2 Resolutions of Assumption Violations

- Verify the Linear Relationships again. (non-linear regression, generalized linear models)
- Transformations (for outliers, heteroskeasticities, etc)
- Use different models on different periods/data
- Weighted **Least Squares regression**, **Robust Regression** (for outliers, heteroskeasticity)

6.2.3 Interpretaion

Under Normal Condition, we have

$$y \sim N(\beta_0 + \beta_1 x_i, \sigma^2), L(\theta) = \left(\frac{1}{\sqrt{2\pi}\sigma} \right)^n \exp\left(-\frac{\sum_{i=1}^n (y_i - (\beta_0 + \beta_1 x_i))^2}{2\sigma^2}\right)$$

Equivalent to minimize

$$RSS(\theta) = \sum_{i=1}^n (y_i - (\beta_0 + \beta_1 x_i))^2$$

$$\partial_{\beta_i} RSS = 0, i = 1, 2$$

, we get

$$r_{xy} = \frac{s_{xy}}{s_x s_y}, \beta_1 = r_{xy} \frac{s_y}{s_x} = \frac{s_{xy}}{s_x^2}, \beta_0 = \bar{y} - \hat{\beta} \bar{x}$$

In Multi-variate Case:

$$f(x) = \mathbf{w}^T \mathbf{x} = \sum_{i=1}^n w_i x_i$$

$$\mathbf{w}^* = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$$

Assuming noise is normal, maximize

$$p(\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_n | \mathbf{w}) = \prod_k \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2\sigma^2} (y_k - \mathbf{w}_t^T \mathbf{x}_k)^2\right]$$

Another matrix representation

$$f(\beta) = \min(Y - X\beta)^T (Y - X\beta), f'(\beta) = 2X^T (Y - X\hat{\beta}) = 0$$

to solve $\hat{\beta}$

$$\min ||y_k - \mathbf{w}^T \mathbf{x}_k||^2 + \lambda ||\mathbf{w}||_1$$

Variance Error In Prediction

$$\begin{aligned} V(\hat{y}^* - y^*) &= \sigma^2 + \sigma^2 \left[\frac{1}{n} + \frac{(x^* - \bar{x})^2}{(n-1)s_x^2} \right] \\ &= V(E(y^*) - y^*) + V(\hat{y}^* - E(y^*)) + 2\text{cov}(\hat{y}^* - y^*, \hat{y}^* - y^*) \end{aligned}$$

The cross term is zero, the first term is variance with ε^* , second term is variance in β .

The confidence interval is $\hat{y}^* \pm t_{\alpha/2, n-2} SE(\hat{y}^*)$.

R^2 , the coefficient of determination: The proportion of the sum of squared response which is accounted by the model relative to the model with no covariance. (take mean of response)

$$R^2 = 1 - \frac{\sum (y_i - \hat{y}_i)^2}{\sum (y_i - \bar{y})^2}$$

Note that $0 \leq R^2 \leq 1$ It only tells predictive power if the model is a good fit.

Hat Matrix: The relationship of predicted value and response

$$\hat{Y} = H Y$$

$$H = X(X^T X)^{-1} X^T$$

The Diagonal Entries h_{ii} are the Leverages.

6.2.4 Model Selection and Overfitting Resolve

- Exhaustive Search by AIC or BIC (more stable than LOOCV)
- Stepwise Regression/Stepwise Variable Selection (At each step one covariate is added or dropped)
- Cross-Validation
Leave-one-Out cross Validation of Linear Regression: Prediction Error Sum of Squares

$$PRESS = \frac{\sum (y_i - \hat{y}_{-i})^2}{n}$$

$$y_i - \hat{y}_{-i} = \frac{\hat{\varepsilon}_i}{1 - h_{ii}}$$

h is the leverage (hat matrix)

6.3 Multiple Linear Regression

6.3.1 Lasso-Least Absolute Shrinkage and Selection Operator

6.4 Regularization, Ridge and Lasso

6.5 Practice/Examples

1. What is Anscombe's Quartet

Chapter 7

Logistic Regression and Generalized Linear Model

Intuition About Logit and Logistic Functions:

We want to predict some values so that

$$\sigma(z) = \frac{1}{1 + e^z}$$

Loss Function

$$J(z) = -y \log y + (1 - y) \log(1 - y)$$
